ARTICLES OF INTEREST – June 2019

Development of nationwide recommendations to support prenatal counseling in extreme prematurity

The authors sought to develop a nationwide, evidence-based framework to support prenatal counseling in extreme prematurity. A nationwide multicenter RAND-modified Delphi method study was performed between November 2016 and December 2017 in the Netherlands. A total of 101 recommendations were included in the framework, including tools to support personalization. A nationwide, evidence-based framework for prenatal counseling in extreme prematurity was developed containing recommendations and tools for personalization in the domains of organization, decision-making, content, and style of prenatal counseling.

Effect of early versus delayed cord clamping in neonate on heart rate, breathing and oxygen saturation during first 10 minutes of birth - randomized clinical trial (PDF)

The authors sought to evaluate the effect of delayed (≥180 s) versus early (≤60 s) cord clamping on peripheral blood oxygenation and heart rate up to 10 min after birth on term and late preterm infants. Spontaneously breathing babies subjected to DCC have higher oxygen saturation up to 10 min after birth compared to those who have undergone ECC. Spontaneously breathing babies with DCC have lower heart rates compared to ECC until 390 s. Spontaneously breathing babies receiving DCC have early establishment of breathing compared to ECC.

Mild neonatal brain hypoxia-ischemia in very immature rats causes long-term behavioral and cerebellar abnormalities at adulthood

In order to evaluate long-term impact of hypoxia-ischemia (HI) the authors measured behavior, alterations in vivo 1H magnetic resonance spectroscopy (1H MRS) and molecular changes to the cerebellum in adult rats after mild early postnatal HI. They found that HI induces hyperactivity toward adulthood, long-lived neuro-metabolic change, and substantial decreases of expression of neuronal and
myelin markers in the cerebellum of adult rats. Taken together, the data provides in vivo evidence of long-term neurologic changes in the cerebellum following mild neonatal HI.

**Prophylactic postnatal corticosteroids: early hydrocortisone**
Baud O and Watterberg KL. *Semin Fetal Neonatal Med.*

The authors review and summarize four randomised clinical trials enrolling almost 1000 extremely preterm infants, treated prophylactically with low-dose hydrocortisone. These studies show significantly decreased BPD and mortality, reduced need for medical treatment for the PDA, no increase in GI perforation in the absence of indomethacin, but an increase in late-onset sepsis. They conclude that the effects of early low-dose hydrocortisone make a strong case for its use in extremely preterm infants at high risk for BPD.

**Oxygen desaturations in the early neonatal period predict development of bronchopulmonary dysplasia**

This is a single-center retrospective descriptive study quantifying bradycardia (HR <100 for ≥ 4 seconds), desaturation (SpO2 <80% for ≥ 10 seconds) events, and percent time spent in events in VLBW infants (23-33wks) in the first 4 weeks of life. The study tested logistic regression models of clinical risks to estimate the risks of BPD or death and secondary outcomes. The primary outcome of BPD was noted in 187 of 502 infants (37%). The study concluded that oxygen desaturations in the first four weeks of life are associated with increased risk of BPD as well as other comorbidities (severe IVH, ROP, prolonged length of stay).

**Prolonged duration of early antibiotic therapy in extremely premature infants**

This is a multicenter cohort study of prolonged early antibiotic use (≥5days, started ≤72hrs of age) in preterm infants 22-28wk gestation (birth weight 401-1000g) from 13 centers during 2008–2014 and survived ≥5 days without culture-confirmed infection, NEC, or spontaneous intestinal perforation. Among 5730 infants who met inclusion criteria, prolonged antibiotic use declined from 49% in 2008 to 35% in 2014. The study showed that prolonged early antibiotics were not significantly associated with increased odds of death (p = 0.07) or NEC. The authors concluded that significant center variation persists with prolonged early antibiotic use.

**Cost effectiveness of neonatal resuscitation at 22 weeks of gestation**

A decision-analytic model was used to evaluate the cost of care of infants born at 22 weeks in the United States. Three resuscitation strategies were compared: universal resuscitation, selective resuscitation, or no resuscitation. Outcomes of death and survival with and without impairment were compared over the infant’s predicted lifetime with cost data including healthcare costs and estimated quality of life for mother and child. In a one-year model of 22-week births, a predicted cohort of 5,176 neonates receiving universal resuscitation would result in 365 additional survivors at a cost of $465 million over no resuscitation. Selective resuscitation would also increase survival by 70 at a cost of $130 million. Both universal and selective resuscitation increased neonatal quality of life but decreased
maternal quality of life. The authors conclude that no resuscitation is currently the most cost-effective strategy for 22-week births.

Effects of a new device for automated closed loop control of inspired oxygen concentration on fluctuations of arterial and different regional organ tissue oxygen saturations in preterm infant

The authors tracked oxygen saturation for 12 VBLW babies in a crossover study to assess the effectiveness of an integrated automated oxygen control on the Sophie Infant Ventilator compared to manual oxygen adjustment by the bedside staff. 2 babies were intubated, 3 were on non-invasive PPV, and 7 were on CPAP. Infants were randomly assigned to automated or manual control for 24 hours; then each patient crossed over to the opposite arm for 24 hours. Automated control increased the time spent within target saturation range, decreased hypoxemia, decreased the number of prolonged (>60s) hypoxemic events, and decreased the number of manual adjustments. Regional tissue oxygenation was unaffected.

Physiological-based cord clamping in preterm infants using a new purpose-built resuscitation table: a feasibility study

This single-center observational study included 37 infants born less than 35 weeks’ gestational age. Infants were stabilized on a purpose-built resuscitation table (Concord) and cord clamping was performed when the infant was stable (HR >100 bpm, spontaneous breathing on CPAP with tidal volumes >4 mL/kg, SpO2 ≥25th% and FiO2<0.4). Physiologic-based cord clamping was successful in 33 infants (89.2%) and resulted in median (IQR) cord clamping time of 4:23 (3:00-5:11) min after birth. There were no maternal or neonatal adverse events. The authors concluded that physiologic-based cord clamping is feasible in preterm infants

Hyperglycemia and glucose variability are associated with worse brain function and seizures in neonatal encephalopathy: a prospective cohort study

In a prospective cohort study of 45 infants, the authors investigated the correlation between glucose abnormalities measured using continuous interstitial glucose monitors and aEEG in the first 3 days in infants with neonatal encephalopathy. Several episodes of hypoglycemia (≤50 mg/dL; ≤2.8 mmol/L) and hyperglycemia (>144 mg/dL; >8.0 mmol/L) were identified. Epochs of hypoglycemia were not associated with aEEG changes. Compared with epochs of normoglycemia, epochs of hyperglycemia were associated with worse aEEG background scores, less sleep-wake cycling and more EEG seizures after adjusting for severity. The authors concluded that in neonates with encephalopathy, epochs of hyperglycemia were temporally associated with worse global brain function and seizures, either reflecting severe brain damage or by causing direct neuronal injury.
Donor human milk and risk of surgical necrotizing enterocolitis: A meta-analysis

Several published meta-analysis have evaluated the protective effect of donor banked milk (DM) on overall incidence of NEC, but none so far focused on the risk of surgical NEC in infants receiving DM. In this meta-analysis, the authors identified 4 relevant manuscripts. Estimates were pooled using random-effects. Study quality was assessed by GRADE score and risk of bias by the Review Manager software tool. They concluded that DM did not exert a clear protective effect on risk of preventing surgical NEC compared to formula.
